

# From Context-Free Grammars to Parsers

Eelco Visser

CS4200 | Compiler Construction | October 14, 2021

# This Lecture

## Derivations

- Generating sentences and trees from context-free grammars

## Reductions

- From sentences to symbols

## Parsing

- Shift/reduce parsing
- SLR parsing

# Reading Material

These slides are the primary material for study of parsing in this course.

This provides a basic idea of parsing by studying derivations and one particular parsing algorithm.

It is by no means exhaustive.

There is a vast literature on parsing, and we encourage the interested student to read on.

## Parsing

Second Edition

The perspective of this lecture on declarative syntax definition is explained more elaborately in this Onward! 2010 essay. It uses an older version of SDF than used in these slides. Production rules have the form

$X_1 \dots X_n \rightarrow N \{cons("C")\}$

instead of

$N.C = X_1 \dots X_n$

### Abstract

Syntax definitions are pervasive in modern software systems, and serve as the basis for language processing tools like parsers and compilers. Mainstream parser generators pose restrictions on syntax definitions that follow from their implementation algorithm. They hamper evolution, maintainability, and compositionality of syntax definitions. The pureness and declarativity of syntax definitions is lost. We analyze how these problems arise for different aspects of syntax definitions, discuss their consequences for language engineers, and show how the pure and declarative nature of syntax definitions can be regained.

### Prologue

In the beginning were the *words*, and the words were *trees*, and the trees were words. All words were made through *grammars*, and without grammars was not any word made that was made. Those were the days of the garden of Eden. And there where language engineers strolling through the garden. They made languages which were sets of words by making grammars full of beauty. And with these grammars, they turned words into trees and trees into words. And the trees were natural, and pure, and beautiful, as were the grammars.

Among them were software engineers who made software as the language engineers made languages. And they dwelt with them and they were one people. The language en-

gineers were software engineers and the software engineers were language engineers. And the language engineers made *language software*. They made *recognizers* to know words, and *generators* to make words, and *parsers* to turn words into trees, and *formatters* to turn trees into words.

But the software they made was not as natural, and pure, and beautiful as the grammars they made. So they made software to make language software and began to make language software by making *syntax definitions*. And the syntax definitions were grammars and grammars were syntax definitions. With their software, they turned syntax definitions into language software. And the syntax definitions were language software and language software were syntax definitions. And the syntax definitions were natural, and pure, and beautiful, as were the grammars.

**The Fall** Now the serpent was more crafty than any other beast of the field. He said to the language engineers,

*Did you actually decide not to build any parsers?*

And the language engineers said to the serpent,

*We build parsers, but we decided not to build others than general parsers, nor shall we try it, lest we loose our syntax definitions to be natural, and pure, and beautiful.*

But the serpent said to the language engineers,

*You will not surely loose your syntax definitions to be natural, and pure, and beautiful. For you know that when you build particular parsers your benchmarks will be improved, and your parsers will be the best, running fast and efficient.*

So when the language engineers saw that restricted parsers were good for efficiency, and that they were a delight to the benchmarks, they made software to make efficient parsers and began to make efficient parsers by making *parser definitions*. Those days, the language engineers went out from the garden of Eden. In pain they made parser definitions all the days of their life. But the parser definitions were not grammars and grammars were not parser definitions. And by the sweat of their faces they turned parser definitions into effi-

This PhD thesis presents a uniform framework for describing a wide range of parsing algorithms.

“Parsing schemata provide a general framework for specification, analysis and comparison of (sequential and/or parallel) parsing algorithms. A grammar specifies implicitly what the valid parses of a sentence are; a parsing algorithm specifies Elicitly how to compute these. Parsing schemata form a well-defined level of abstraction in between grammars and parsing algorithms. A parsing schema specifies the types of intermediate results that can be computed by a parser, and the rules that allow to Eand a given set of such results with new results. A parsing schema does not specify the data structures, control structures, and (in case of parallel processing) communication structures that are to be used by a parser.”

## Parsing Schemata

Klaas Sikkel

This paper applies parsing schemata to disambiguation filters for priority conflicts.

# A Case Study in Optimizing Parsing Schemata by Disambiguation Filters

Eelco Visser

## Abstract

Disambiguation methods for context-free grammars enable concise specification of programming languages by ambiguous grammars. A disambiguation filter is a function that selects a subset from a set of parse trees—the possible parse trees for an ambiguous sentence. The framework of filters provides a declarative description of disambiguation methods independent of parsing. Although filters can be implemented straightforwardly as functions that prune the parse forest produced by some generalized parser, this can be too inefficient for practical applications.

In this paper the optimization of parsing schemata, a framework for high-level description of parsing algorithms, by disambiguation filters is considered in order to find efficient parsing algorithms for declaratively specified disambiguation methods. As a case study the optimization of the parsing schema of Earley's parsing algorithm by two filters is investigated. The main result is a technique for generation of efficient LR-like parsers for ambiguous grammars modulo priorities.

## 1 Introduction

The syntax of programming languages is conventionally described by context-free grammars. Although programming languages should be unambiguous, they are often described by ambiguous grammars because these allow a more natural formulation and yield better abstract syntax. For instance, the grammar

$$E \rightarrow E + E; E \rightarrow E * E; E \rightarrow a$$

gives a clearer description of arithmetic expressions than the grammar

$$E \rightarrow E + T; E \rightarrow T; T \rightarrow T * a; T \rightarrow a$$

To obtain an unambiguous specification of a language described by an ambiguous grammar it has to be disambiguated. For example, the grammar above can be disambiguated by associativity and priority rules that express that  $E \rightarrow E * E$  has higher priority than  $E \rightarrow E + E$  and that both productions are left associative.

This is an extended version of [Vis95].

This paper defines a declarative semantics for associativity and priority declarations for disambiguation.

The paper provides a safe semantics and extends it to deep priority conflicts.

The result of disambiguation is a contextual grammar, which generalises the disambiguation for the dangling-else grammar.

For the interested

The paper is still in production. Ask me for a copy of the draft.

## A Direct Semantics for Declarative Disambiguation of Expression Grammars

LUIS EDUARDO S. AMORIM, Delft University of Technology

TIMOTHÉE HAUDEBOURG, Université Rennes, Inria, IRISA

MICHAEL J. STEINDORFER, Delft University of Technology

EELCO VISSER, Delft University of Technology

Associativity and priority rules provide a mechanism for disambiguation of context-free grammars that is based on concepts familiar to programmers from high-school mathematics. However, there is no standardized and declarative semantics for such rules, in particular for the disambiguation of the more complex expression grammars encountered in programming languages.

In this paper, we provide a *direct* semantics of disambiguation of *expression grammars* by means of associativity and priority declarations by defining the subtree exclusion patterns corresponding to each declaration. We introduce *deep priority conflicts* to solve ambiguities that cannot be captured by fixed-depth patterns such as ambiguities due to low priority prefix or postfix operators, dangling prefix, dangling suffix, longest match, and indirect recursion. We prove that the semantics is *safe* (preserves the language of the underlying context-free grammar) and *complete* (solves all ambiguities) for classes of expression grammars of increasing complexity that have only *harmless overlap*, provided a total set of disambiguation rules is provided.

We define a canonical implementation that transforms a grammar with disambiguation rules into a disambiguated grammar. We also describe alternative implementations that interpret disambiguation rules during parser generation or during parsing. We have evaluated the approach by applying it to the grammars of five languages. Finally, we demonstrate that our approach is practical by measuring the performance of a parser that implements our disambiguation techniques, applying it to a corpus of real-world Java and OCaml programs.

# Parser Architecture

# Traditional Parser Architecture

# Context-Free Grammars

## Terminals

- Basic symbols from which strings are formed

## Nonterminals

- Syntactic variables that denote sets of strings

## Start Symbol

- Denotes the nonterminal that generates strings of the languages

## Productions

- $A = X \dots X$
- Head/left side ( $A$ ) is a nonterminal
- Body/right side ( $X \dots X$ ) zero or more terminals and nonterminals

# Example Context-Free Grammar

```
grammar
  start S
  non-terminals E T F
  terminals "+" "*" "(" ")" ID
  productions
    S = E
    E = E "+" T
    E = T
    T = T "*" F
    T = F
    F = "(" E ")"
    F = ID
```

# Abbreviated Grammar

```
grammar
start S
non-terminals E T F
terminals "+" "*" "(" ")" ID
productions
S = E
E = E "+" T
E = T
T = T "*" F
T = F
F = "(" E ")"
F = ID
```

```
grammar
productions
S = E
E = E "+" T
E = T
T = T "*" F
T = F
F = "(" E ")"
F = ID
```

Nonterminals, terminals can be derived from productions

First production defines start symbol

# Notation

$A, B, C$  : non-terminals

$l$  : terminals

$\alpha, \beta, \gamma$  : strings of non-terminals and terminals

$w, v$  : strings of terminal symbols

Is there a production in the grammar that matches the top of the stack?

How to choose between possible shift and reduce actions?

## LR(k) Parsing

- L: left-to-right scanning
- R: constructing a right-most derivation
- k: the number of lookahead symbols

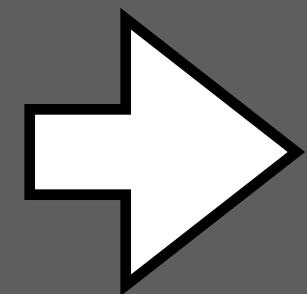

## Motivation for LR

- LR grammars for many programming languages
- Most general non-backtracking shift-reduce parsing method
- Early detection of parse errors
- Class of grammars superset of predictive/LL methods

## SLR: Simple LR

# Item

$E = E \ " + " \ T$

$[E = . \ E \ " + " \ T]$

$[E = E \ . \ " + " \ T]$

$[E = E \ " + " \ . \ T]$

$[E = E \ " + " \ T \ .]$

We expect to see an expression

We have seen an expression  
and may see a “+”

# Production

# Items

Item indicates how far we have progressed in parsing a production

# Item Set

# Parsing: Summary

## Context-free grammars

- Productions define how to generate sentences of language
- Derivation: generate sentence from (start) symbol
- Reduction: reduce sentence to (start) symbol

## Parse tree

- Represents structure of derivation
- Abstracts from derivation order

## Parser

- Algorithm to reconstruct derivation

## First/Follow

- Selecting between actions in LR parse table

# More Topics in Syntax and Parsing

## Other algorithms

- Top-down: LL( $k$ ) table
- Generalized parsing: Earley, Generalized-LR
- Scannerless parsing: characters as tokens

## Disambiguation

- Semantics of declarative disambiguation
- Deep priority conflicts
